## Driving the expression of the *Salmonella enterica* sv Typhimurium flagellum using *flhDC* from *Escherichia coli* results in key regulatory and cellular differences

Ayman Albanna<sup>1,2,6</sup>, Martin Sim<sup>1,2,7</sup>, Paul A. Hoskisson<sup>3</sup>, Colin Gillespie<sup>4</sup>, Christopher V. Rao<sup>5</sup> & Phillip D. Aldridge<sup>1,2</sup>

The flagellar systems of *Escherichia coli* and *Salmonella enterica* exhibit a significant level of genetic and functional synteny. Both systems are controlled by the flagellar specific master regulator FlhD<sub>4</sub>C<sub>2</sub>. Since the early days of genetic analyses of flagellar systems it has been known that *E. coli flhDC* can complement a  $\Delta flhDC$  mutant in *S. enterica*. The genomic revolution has identified how genetic changes to transcription factors and/or DNA binding sites can impact the phenotypic outcome across related species. We were therefore interested in asking: using modern tools to interrogate flagellar gene expression and assembly, what would the impact be of replacing the *flhDC* coding sequences in *S. enterica* for the *E. coli* genes at the *flhDC S. enterica* chromosomal locus? We show that even though all strains created are motile, flagellar gene expression is measurably lower when *flhDC<sub>EC</sub>* are present. These changes can be attributed to the impact of FlhD<sub>4</sub>C<sub>2</sub> DNA recognition and the protein-protein interactions required to generate a stable FlhD<sub>4</sub>C<sub>2</sub> complex. Furthermore, our data suggests that in *E. coli* the internal flagellar FliT regulatory feedback loop has a marked difference with respect to output of the flagellar systems. We argue due diligence is required in making assumptions based on heterologous expression of regulators and that even systems showing significant synteny may not behave in exactly the same manner.

The flagellum in the enteric bacteria, *Escherichia coli* and *Salmonella enterica*, has been studied extensively for over fifty years and provides the canonical example for bacterial motility. These studies have revealed not only the complex structure of the enteric flagellum but also its role in host colonization, pathogenesis, and cellular physiology<sup>1–4</sup>. In addition, these studies have identified many of the complex regulatory processes that coordinate the assembly and control of this exquisitely complex biological machine<sup>3–5</sup>.

The flagellum in *E. coli* and *S. enterica* are structurally very similar and are often tacitly assumed to be effectively identical aside from differences in the filament structure. However, in the case of regulation, these assumptions are based more on sequence similarity rather than on actual experimental data<sup>5,6</sup>. Indeed, a number of studies have shown that these two systems are regulated in entirely different manners in response to environmental signals despite strong gene synteny. For example, many common *E. coli* strains are motile only during growth in nutrient-poor conditions whereas many common *S. enterica* strains are motile only during growth in

nutrient-rich conditions<sup>7</sup>. In addition, *E. coli* is more motile at 30 °C than at 37 °C whereas motility *S. enterica* is generally insensitive to these temperature differences<sup>8</sup>. *E. coli* *flhDC* are transcribed from a single transcriptional start site that is responsive to OmpR, RcsB and CRP regulation, to name only a few regulatory inputs<sup>8</sup>. In contrast *S. enterica* *flhDC* transcription is significantly more complex with up to 5 transcriptional start sites, albeit with only a subset being responsible for the majority of *flhDC* transcription<sup>9</sup>.

Part of the problem is that different questions have been asked when studying the regulation of motility in these two bacterial species. Most studies in *E. coli* have focused on the environmental signals and associated regulatory process that induce bacterial motility. In particular, they have focused on the processes that regulate the expression of the master flagellar regulator, FlhD<sub>4</sub>C<sub>2</sub><sup>8</sup>. Most studies in *S. enterica*, on the other hand, have focused on the regulatory processes that coordinate the assembly process following induction<sup>4</sup>. In particular, they have focused on the downstream regulatory processes induced by FlhD<sub>4</sub>C<sub>2</sub><sup>3</sup>.

Despite differences in regulation, the protein subunits of master flagellar regulators, FlhC and FlhD, exhibit high sequence similarity sharing 94 and 92% identity, respectively (Figure S1), between *E. coli* and *S. enterica*. For both proteins the most significant amino acid changes are within the last 8 amino acids. Other substitutions are scattered across each protein and do not provide a consistent mutational pattern that provide a clear phenotypic explanation. Given that modifications to transcription factors and/or promoter structure can lead to divergence in regulatory circuits<sup>10</sup>, we were interested in how FlhD<sub>4</sub>C<sub>2</sub> functions in different genetic backgrounds. Previously, it was shown that *E. coli* *flhDC* can complement a  $\Delta$ *flhDC* mutant in *S. enterica*, suggesting that these proteins are functionally identical in the two bacterial species<sup>11</sup>. However, it is not clear whether they are regulated in the same manner. We, therefore, investigated the impact of replacing the native master regulator in *S. enterica* with the one from *E. coli*. Defining the impact of known FlhD<sub>4</sub>C<sub>2</sub> regulators such as ClpP, RflP (previously known as YdiV), FliT and FliZ on the two complexes suggest that these two species have adapted in how they perceive FlhD<sub>4</sub>C<sub>2</sub>. We argue that these phenotypic differences arise from adaptations *E. coli* and *S. enterica* have made during evolution to expand or modify cellular function with respect to movement within specific environmental niches.

## Results

**Orthologous *flhDC* from *E. coli* can functionally complement *flhDC* in *S. enterica*.** Given the similarities between the flagellar systems in *S. enterica* and *E. coli*, we sought to determine whether the FlhD<sub>4</sub>C<sub>2</sub> master regulator is functionally equivalent in these two species of bacteria. To test this hypothesis, we replaced the *flhDC* genes in *S. enterica* (*flhDC*<sub>SE</sub>) with the *flhDC* genes from *E. coli* (*flhDC*<sub>EC</sub>). The reason that we performed these experiments in *S. enterica* rather than *E. coli* was that the flagellar system is better characterized in the former, particularly with regards to transcriptional regulation. To avoid plasmid associated artefacts associated with the ectopic expression of *flhDC*, we replaced the entire *S. enterica* *flhDC* operon with the *flhDC* operon from *E. coli* at the native chromosomal locus (Figure S2).

We first tested whether *flhDC*<sub>EC</sub> was motile as determined using soft-agar motility plates. As shown in Fig. 1A and B, these strains formed rings similar to the wild type. These results demonstrate that *flhDC*<sub>EC</sub> is functional in *S. enterica*. However, motility plates measure both motility and chemotaxis and do not provide any insights regarding possibly changes in the number of flagella per cell. To determine the impact *flhDC*<sub>EC</sub> had upon flagellar numbers we used a FliM-GFP fusion as a proxy for flagellar numbers (Fig. 1C). When this fluorescent protein fusion is expressed in cells, it forms spots associated with nascent C-rings that loosely correlate with the number of flagella<sup>12–14</sup>. By counting the number of spots per cell, we can determine the number of flagella made per cell. As shown in Fig. 1C, *flhDC*<sub>EC</sub> did not change flagellar numbers as compared to the wild type. These results demonstrate *flhDC*<sub>EC</sub> induces flagellar gene expression at similar levels as the wild type.

***flhDC* requires a specific transcription rate to maintain optimal flagellar numbers.** The flagellar network in *S. enterica* contains a number of feedback loops to ensure that the cells regulate the number of flagella produced<sup>4</sup>. One possibility is that these feedback loops mask any differences in FlhD<sub>4</sub>C<sub>2</sub> activity. To test this hypothesis, we replaced the native *P*<sub>flhD</sub> promoter with the tetracycline-inducible *P*<sub>tetA/tetR</sub> promoters. We then measured flagellar gene expression using a luciferase reporter system<sup>15</sup>. In this case, a consistent and significant change (e.g. at 10 ng for *P*<sub>flgA</sub> ANOVA *P* = 0.0008) in flagellar gene expression was observed when comparing activity across all strains tested (Fig. 2A and B). Maximal expression of *P*<sub>flgA</sub> and *P*<sub>fliC</sub>, chosen to reflect flagellar gene expression at different stages of flagellar assembly<sup>5</sup>, for both complexes was observed between 10 and 25 ng/ml of anhydrotetracycline, when *flhDC* transcription was from *P*<sub>tetA</sub> (Fig. 2A and B). In contrast, *P*<sub>tetR</sub>, the weaker of the two tetracycline inducible promoters, reached a maximal output between 50 to 100 ng/ml anhydrotetracycline. When comparing *P*<sub>tetA</sub> and *P*<sub>tetR</sub> activity around the transition points in each experiment, for example 10 ng anhydrotetracycline for *P*<sub>flgA</sub>, the difference between *P*<sub>tetA</sub> and *P*<sub>tetR</sub> expression was significant (see Fig. 2 legend for *P*-values). However, the observed differences between FlhD<sub>4</sub>C<sub>2</sub>EC to FlhD<sub>4</sub>C<sub>2</sub>SE for either *P*<sub>tetA</sub> or *P*<sub>tetR</sub> expression were not significant (e.g. at 10 ng for *P*<sub>flgA</sub> via *P*<sub>tetA</sub> expression ANOVA *P* = 0.186).

We also measured the number of FliM-GFP foci at different anhydrotetracycline concentrations. *P*<sub>tetR::flhDC</sub> expression generated on average of approximately two FliM-foci per cell at 25 ng/ml of anhydrotetracycline for both FlhD<sub>4</sub>C<sub>2</sub> complexes (Fig. 2C). In contrast, 5 ng/ml induction of the *P*<sub>tetA::flhDC</sub>EC strain was sufficient to generate typical FliM-foci numbers (approx. 8 flagellar foci per cell). These data reflect the statistical significance of the expression data where a marked difference between *P*<sub>tetA</sub> and *P*<sub>tetR</sub> expression was observed (Fig. 2A and B). Even with the strong decrease in average foci per cell at these levels of induction for *P*<sub>tetR</sub>, the number of basal bodies observed is sufficient to allow motility at comparable levels in the motility agar assay (Figure S3).

**Replacement of *flhC* but not *flhD* in *S. enterica* with the *E. coli* orthologs affects motility.** The hetero-oligomeric regulator FlhD<sub>4</sub>C<sub>2</sub> is unusual in bacteria as the majority of transcriptional regulators are believed to be homo-oligomeric complexes. To determine the relative contributions of the two subunits, we

**Figure 1.** (A) Motility of  $flhDC_{ST}$  and  $flhDC_{EC}$  driven by  $P_{flhDC}$ . (B) Quantification of swarms produced in motility agar after 6 to 8 hours incubation. Error bars indicate calculated standard deviations. (C) Percentage frequency of FliM-GFP foci for  $flhDC_{EC}$  compared to *S. enterica* with  $flhDC$  under the control of  $P_{flhDC}$ . Colors of bars in the graph correspond to the source of  $flhDC$  as shown in (B).

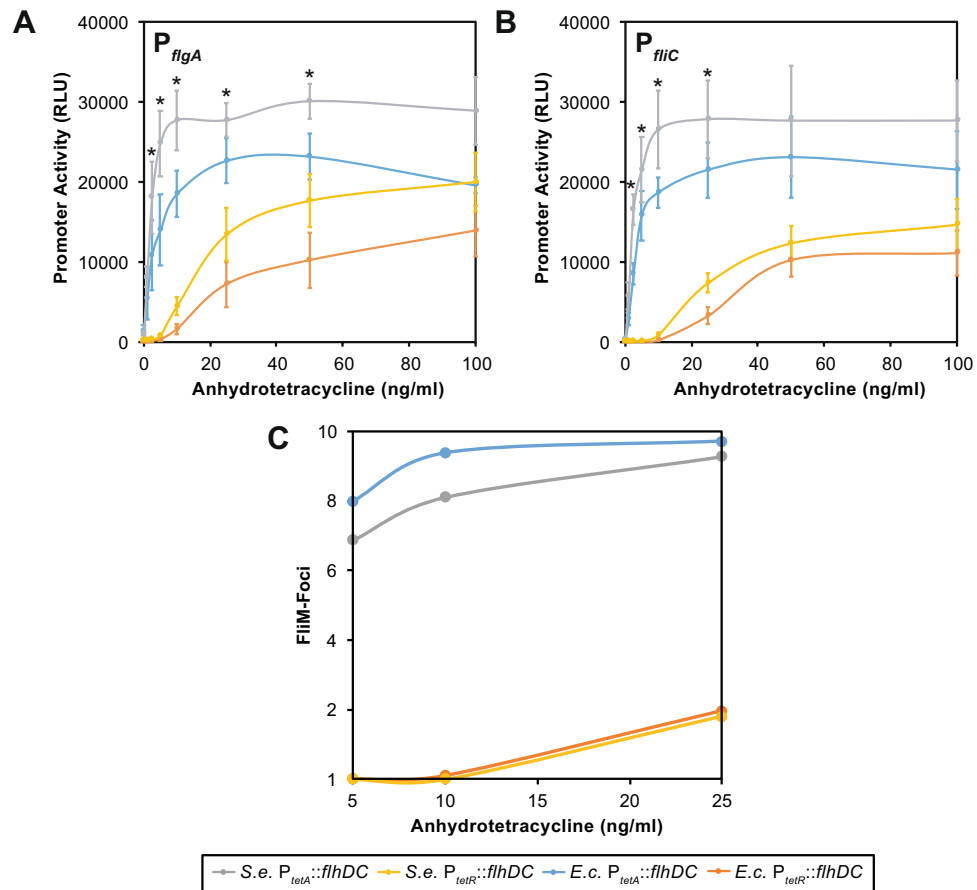

individually replaced the  $flhC$  or  $flhD$  genes from *S. enterica* with their ortholog from *E. coli* (Figure S2). When we tested the two strains using motility plates, we found that motility was inhibited in the strain where  $flhC_{EC}$  replaced the native *S. enterica*  $flhC$  (Fig. 3A; blue bars), with an 88% reduction in swarm diameter when compared to WT *S. enterica*. The introduction of  $flhD_{EC}$  compared to  $flhDC_{EC}$  or  $flhDC_{SE}$  produced swarms of a comparable size (Fig. 3A; blue bars).

Using the dose-dependent inducible  $P_{tetA}$  promoter<sup>16</sup> we observed that  $P_{tetA}$  expression of  $flhC_{EC}$  led to reduced  $P_{flgA}$  transcription and strongly reduced  $P_{flhC}$  transcription (Fig. 4). Strains expressing  $flhD_{EC}$  in *S. enterica* showed a mild increase in  $P_{flgA}$  gene expression and a similar response for  $P_{flhC}$ , although these changes were not significant (see Fig. 4 for P values). These data suggest that the combination of FlhD<sub>SE</sub> and FlhC<sub>EC</sub> generates an inefficient FlhD<sub>4</sub>C<sub>2</sub> complex, resulting in reduced motility.

#### Orthologous FlhC and FlhD interaction is species specific and a key determinant of promoter recognition by the FlhD<sub>4</sub>C<sub>2</sub> complex.

The results above demonstrate that  $flhC_{EC}$  is not functionally identical to  $flhC_{ST}$ . One possibility is that FlhC<sub>EC</sub> is impaired in FlhD<sub>4</sub>C<sub>2</sub> for DNA-binding. Alternatively, the stability of the FlhD<sub>4</sub>C<sub>2</sub> complex is reduced in the  $flhC_{EC}$  strain, leading to reduced FlhD<sub>4</sub>C<sub>2</sub> activity. To test these hypotheses, we purified all combinations of the FlhD<sub>4</sub>C<sub>2</sub> complex using affinity (Ni<sup>2+</sup> and heparin) chromatography (Fig. 5A). In each complex, FlhD was tagged with a carboxy-terminal hexa-histidine to facilitate affinity purification. Such expression constructs have previously been used successfully to purify the FlhD<sub>4</sub>C<sub>2</sub> complex<sup>17,18</sup>. Using either Ni<sup>2+</sup> affinity or heparin purification, we observed complete complex retrieval for three combinations (Fig. 5A). FlhC recovery was less efficient in the FlhD<sub>SE</sub>/FlhC<sub>EC</sub> complex. In contrast, no FlhD<sub>SE</sub>/FlhC<sub>EC</sub> complex was recovered via Heparin purification, used to mimic DNA during protein purification of DNA-binding proteins (Fig. 5A). This suggests that the FlhD<sub>SE</sub>/FlhC<sub>EC</sub> complex is less stable, resulting on a lower yield of complex retrieval.

We next used the EMSA assays to test all four protein complexes for their ability to bind the *S. enterica*  $P_{flgAB}$  promoter region. Quantification of the DNA shifts showed that complexes containing the orthologous FlhC<sub>EC</sub> reduced the  $P_{flgAB}$  promoter binding profile, compared to FlhC<sub>SE</sub> complexes (Fig. 5B). This difference is exemplified when calculating the SLOPE (an excel function) of each data set. For FlhD<sub>SE</sub> and FlhD<sub>EC</sub>FlhC<sub>SE</sub> the slopes were −906 and −784 respectively. In comparison FlhD<sub>EC</sub> and FlhD<sub>SE</sub>FlhC<sub>EC</sub> were much shallower at −1570 and −1116 respectively. This is consistent with FlhC being the DNA binding subunit of the complex and the variation

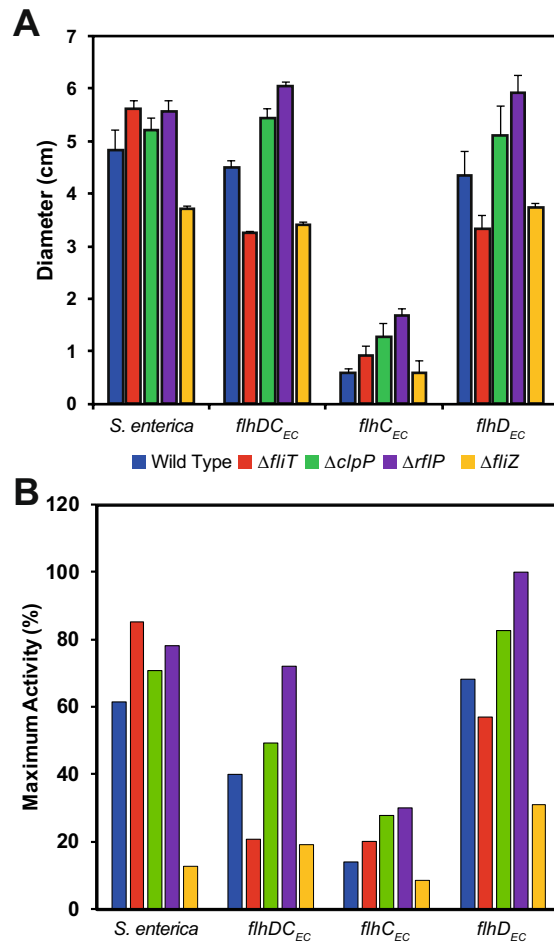

**Figure 2.** Titration of  $P_{tetA}::flhDC_{ST/EC}$  and  $P_{tetR}::flhDC_{ST/EC}$  activity suggests a given rate of transcription drives optimal flagellar assembly. **(A)** Activity of  $P_{flgA}$  in response to  $P_{tetA}$  or  $P_{tetR}$  transcription of  $flhDC$  from *S. enterica* (*S.e.*) or *E. coli* (*E.c.*). Data sets that exhibit statistical significance at  $P < 0.03$  are shown with ‘\*’. Using 10 ng anhydrotetracycline as an example, due to this being where  $FlhD_4C_{2SE}$  reaches maximal activity via  $P_{tetA}$  expression, the following comparisons are significant: *S.e.*  $P_{tetA}$  v  $P_{tetR}$  ( $P = 0.008$ ) *E.c.*  $P_{tetA}$  v  $P_{tetR}$  ( $P = 0.009$ ), while *S.e.*  $P_{tetA}$  v *E.c.*  $P_{tetA}$  is not ( $P = 0.186$ ). Error bars show the standard error of the mean. **(B)** Activity of  $P_{fliC}$  in response to  $P_{tetA}$  or  $P_{tetR}$  transcription of  $flhDC$ . As in (A) the ‘\*’ identifies data sets that exhibit ANOVA statistical significance at  $P < 0.005$ . In agreement with  $P_{flgA}$  activity  $P_{tetA}$  v  $P_{tetR}$  ANOVA comparisons were significant for 5 to 25 ng anhydrotetracycline (e.g. at 10 ng *S.e.*:  $P = 0.012$ ; *E.c.*:  $P = 0.002$ ) while *S.e.*  $P_{tetA}$  v *E.c.*  $P_{tetA}$  comparisons were not. Error bars show the standard error of the mean. **(C)** flagellar numbers as defined by FliM-foci in response to  $P_{tetA}$  or  $P_{tetR}$  transcription of  $flhDC$ . In agreement with the statistical analysis FliM-Foci profiles reflect the statistical significance associated with the expression data shown in (A) and (B). All data represents the analysis of gene expression or FliM-Foci from 3 independent repeats. FliM-Foci data is based on  $n > 400$  cells for each data point. The colours of lines reflect the strains used in Figs 4, 5 and 6, for example in these figures, when graphs are used, *S.e.*  $flhDC$  is represented as gray and its *E.c.*  $flhDC$  replacement as light blue.

in  $FlhD_4C_2$  activated promoter-binding sites between *S. enterica* and *E. coli*<sup>19</sup>. Therefore, these results suggest that FlhC is a key determinant of DNA binding ability. Furthermore, the reduction in  $FlhD_{SE}/FlhC_{EC}$  motility and flagellar gene expression in *S. enterica* is a result of the  $FlhD_{SE}/FlhC_{EC}$  complex being unstable, ultimately reducing the cellular concentration of the  $FlhD_4C_2$  complex.

**FlhD<sub>4</sub>C<sub>2EC</sub> responds to proteolytic regulation.** *S. enterica* and *E. coli* both regulate the  $FlhD_4C_2$  complex through ClpXP-mediated proteolytic degradation. Proteolytic degradation of  $FlhD_4C_2$  plays a fundamental role in facilitating rapid responses to environmental changes that require motility<sup>20,21</sup>. The  $FlhD_4C_2$  complex has a very short half-life of approximately 2–3 minutes<sup>22</sup>. Proteolytic degradation of FlhD and FlhC is regulated in *E. coli* and *S. enterica* by RflP (previously known as YdiV)<sup>23</sup>. However, *rflP* is not expressed under standard laboratory conditions in model *E. coli* strains, suggesting that ClpXP activity is modulated in a species-specific manner<sup>7</sup>.

Previous work has shown that RflP delivers  $FlhD_4C_2$  complexes to ClpXP for degradation<sup>24</sup>. We have assessed the impact on motility for  $\Delta clpP$  and  $\Delta rflP$  mutations (Fig. 3). The  $\Delta clpP$  and  $\Delta rflP$  mutants exhibited improved motility and flagellar gene expression, including the  $FlhD_{SE}/FlhC_{EC}$  strain (Fig. 3A and B). These results suggest that proteolytic degradation mechanism of FlhD and FlhC, and its regulation, is common to *E. coli* and *S. enterica*.

To complement the motility assays, we investigated how  $\Delta clpP$  and  $\Delta rflP$  mutations impact the number of FliM-foci in cell. Both  $\Delta clpP$  and  $\Delta rflP$  mutants showed an increased number of FliM-foci compared to the wild

**Figure 3.** Motility phenotypes and gene expression of *flhDC<sub>ST</sub>*, *flhDCEC*, *flhDEC* and *flhCEC* strains in the absence of known FlhD<sub>4</sub>C<sub>2</sub> regulators. **(A)** Quantification of  $n = 3$  swarms per strain produced in motility agar after 6 to 8 hours incubation at 37 °C. Error bars indicate calculated standard deviations. **(B)** Relative activity of  $P_{flhC}$  in all strains as a percent of the maximal activity observed in *flhDCEC*  $\Delta rfiP$ .

type (Fig. 6A–C). For *flhCEC* strain, FliM-foci were observed in 13% of the population where individual cells exhibited just one or two foci. However, the  $\Delta clpP$  or  $\Delta rfiP$  mutants increased the flagellated population of the *flhCEC* strains to 51 and 46% respectively, albeit with the majority still possessing only a single FliM focus (Fig. 6B and C).

**FliT and FliZ regulation of FlhD<sub>4</sub>C<sub>2</sub> complexes.** FlhD<sub>4</sub>C<sub>2</sub> activity has an additional level of regulation in *S. enterica* via the flagellar-specific regulators FliT and FliZ. FliT functions as an export chaperone for the filament cap protein, FliD, and is a regulator of FlhD<sub>4</sub>C<sub>2</sub> activity<sup>17,25</sup>. FliT disrupts the FlhD<sub>4</sub>C<sub>2</sub> complex but is unable to disrupt a FlhD<sub>4</sub>C<sub>2</sub>:DNA complex. Therefore, FliT modulates availability of FlhD<sub>4</sub>C<sub>2</sub> complexes for promoter binding<sup>17</sup>. In contrast, FliZ is a negative regulator of *rfiP* expression<sup>26,27</sup> and modulates the activity of HilD<sup>28,29</sup> and thus increases the number of FlhD<sub>4</sub>C<sub>2</sub> complexes in *S. enterica*.

In motility assays of  $\Delta fliT$  mutants, we observed a difference between the *flhDC* strains. Motility is increased in a  $\Delta fliT$  mutant background in *S. enterica*<sup>30</sup> (and Fig. 3A). However, when *flhDCEC* and *flhDEC* replaced the native genes, a reduced swarm size was observed (Fig. 3A). Furthermore, quantification of  $P_{flhC}$  activity agreed with the motility profile for  $\Delta fliT$  mutants, where *flhDCEC* and *flhDEC* containing strains had reduced promoter activity compared to wild type (Fig. 3B). This suggests that the FlhD<sub>4</sub>C<sub>2</sub> complexes are being perceived differently by FliT in *S. enterica*. The results for  $\Delta clpP$  and  $\Delta rfiP$  mutants suggest that this is not due to protein stability, as all complex combinations reacted in a comparable fashion (Figs 3 and 6).

In contrast, the loss of *fliZ* resulted in a consistent reduction in motility, except for the *flhCEC* strain. However, as the *flhCEC* strain was already impaired in motility, it is possible that the resolution of the motility assay was unable to identify differences in the  $\Delta fliZ$  mutant. Flagellar gene expression activity did, however, suggest a 2-fold drop in  $P_{flhC}$  expression in the *flhCEC*  $\Delta fliZ$  strain as compared to the otherwise wild-type (Fig. 3B).

Analysis of FliM-foci distribution in  $\Delta fliT$  mutant reinforced the observed discrimination of *flhDCEC* and *flhDEC* gene replacements. Calculating the average foci per cell, *S. enterica*  $\Delta fliT$  mutants showed an increased average number of foci per cell from 2.9 to 6.3, while the *flhDCEC* ( $fliT^+$ : 3.4 versus  $\Delta fliT$ : 4.2) and *flhDCEC* replacements

**Figure 4.** Titration of  $P_{tetA}::flhDC$  for *S. enterica*,  $flhDC_{EC}$ ,  $flhD_{EC}$  and  $flhC_{EC}$  suggests that  $flhC_{EC}$  exhibits low motility due reduced  $P_{flgA}$  activity and a strong reduction in  $P_{fliC}$  activity. Note that the legend indicates which gene has been replaced compared to *S.e. flhDC*. The colours of lines reflect the strains used in Figs 2, 5 and 6, for example in all figures *S.e. flhDC* is represented as gray and the *E.c. flhDC* replacement as light blue. Inducible expression was driven from the  $P_{tetA}$  promoter within the TetRA cassette of Tn10 as in Fig. 2. Data represents  $n = 3$  independent repeats of the expression assays. Data sets exhibiting ANOVA statistical significance of  $P < 0.03$  are indicated with a '\*'. Error bars show the standard error of the mean. The  $P_{flgA}$  variation observed between *S.e. flhDC*, *E.c. flhDC* and *E.c. flhD* at 10 and 25 ng was not significant (ANOVA  $P = 0.64$  and  $0.33$  respectively). In agreement for  $P_{fliC}$  data *S.e. flhDC*, *E.c. flhDC* and *E.c. flhD* exhibits ANOVA  $P$ -values of 10 ng: 0.16 and 25 ng: 0.07. All ANOVA statistical comparisons to *E.c. flhC* were significant  $P < 0.04$ .

( $fliT^+$ : 3.6 versus  $\Delta fliT$ : 2.7) exhibited no significant changes (Fig. 7A). Interestingly, in a  $\Delta fliZ$  mutant background, the FliM-foci analysis was able to differentiate  $flhDC_{EC}$  and  $flhD_{EC}$  from the native *S. enterica flhDC* strain. Both replacements exhibited an increase in the average foci compared to *S. enterica flhDC* (Fig. 7A).

These data suggest that there is a fundamental difference in how the FlhD<sub>4</sub>C<sub>2</sub> complexes in *E. coli* and *S. enterica* respond to, at least, FliT regulation. There are two explanations for this: a) the *E. coli* combinations are being regulated via an unidentified mechanism in *S. enterica* or b) that they are insensitive to FliT regulation. Both arguments predict that in the species *E. coli*, FlhD<sub>4</sub>C<sub>2</sub> may respond differently to FliT regulation. Comparing the species, not gene replacement strains, *S. enterica* and *E. coli* does indeed identify a difference in the response to a  $\Delta fliT$  mutant. While a  $\Delta fliT$  mutant in *S. enterica* leads to a consistent increase in FliM-foci, no significant difference is noted for an *E. coli flhDC* mutant compared to *E. coli* wild type (Fig. 7B). This suggests that the regulatory impact of FliT is very different in these two flagellar systems and the role FliT plays in *S. enterica* is potentially adaptive and species specific.

## Discussion

Two model flagellar systems that form the foundation of the flagellar field are those from the enteric species *E. coli* and *S. enterica*. These two systems have led to key discoveries in relation to many aspects of flagellar structure, type 3 secretion, flagellar cell biology and the regulation of flagellar assembly. Textbook explanations suggest that most flagellar systems are being activated, regulated and built according to the models for *E. coli* and *S. enterica*. Modifications of transcriptional regulatory circuits contribute to the phenotypic diversity we see in closely related gene sets and we are only now able to investigate this in depth due to the tools available. Here we have taken a simple step and asked how do orthologous FlhD<sub>4</sub>C<sub>2</sub> complexes function in the closely related species *E. coli* and *S. enterica*?

At the onset of our work it was known that FlhD<sub>4</sub>C<sub>2</sub> from *E. coli* could sustain motility in *S. enterica*<sup>11</sup>. Our work was focussed on understanding and defining the species-specific differences in the regulon of two orthologous genes. Here we took advantage of the well-defined flagellar assembly tools to measure outputs such as, motility, flagellar assembly per cell and flagellar gene expression. Bioinformatic analysis identifies only an 8 and 6% identity difference between FlhD and FlhC in *E. coli* and *S. enterica* respectively, suggesting that these proteins function in an analogous fashion. It is well established that related taxa usually rely on orthologous regulators to coordinate response to a given signal<sup>10</sup>.

The fine detail of the differences in the FlhD<sub>4</sub>C<sub>2</sub> complexes only became apparent when we began to focus on their effect on flagellar gene expression and flagellar assembly. Biochemical analysis of isolated complexes showed that FlhC<sub>EC</sub> had weaker DNA binding ability to the  $P_{flgAB}$  promoter region from *S. enterica*, consistent with previous investigations into FlhD<sub>4</sub>C<sub>2</sub> DNA binding activity<sup>19</sup>. The isolation of FlhD<sub>4</sub>C<sub>2</sub> complexes from our strains suggested that a key aspect of the phenotypes we observed, was the stability of the complexes formed.

With respect to  $flhDC$  transcription we show a discrepancy in flagellar numbers defined by FliM-foci when using  $P_{tetA}/P_{tetR}::flhDC$  expression. This was somewhat surprising as all constructs exhibited good swarming ability on motility agar plates (Figure S3). Original studies on the regulation of  $P_{tetA}/P_{tetR}$  from Tn10 have shown that these two promoters have differing activities but both respond to TetR regulation. We show that even though

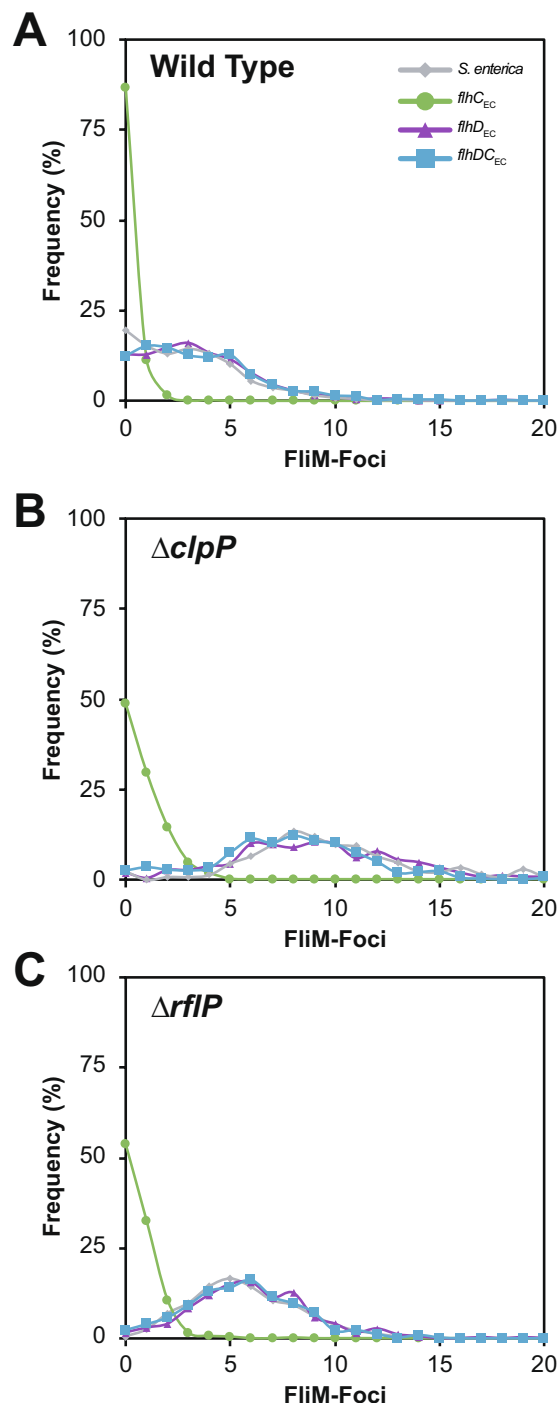

**Figure 5.** The FlhD<sub>ST</sub>-FlhC<sub>EC</sub> complex is an active but unstable complex. **(A)** Protein gel showing purified complexes with either HIS<sub>6</sub> or Heparin based purification protocols. The nature of the FlhDC complex allows isolation of both proteins in these assays. Arrows indicate the FlhC and FlhD bands. The image shown is the complete gel down to the leading edge of the loading buffer. The unprocessed raw image is shown in Figure S4. **(B)** Quantification of the unbound DNA during EMSA to define the binding ability of the complex combinations compared to *S. enterica* FlhD<sub>4</sub>C<sub>2</sub>. The protein complexes used in these assays were isolated via the HIS<sub>6</sub> protocol as indicated in A by the corresponding coloured symbols that act as the key for (B). All colours reflect the same complex associated with data shown in Figs 2, 4 and 6 for continuity, for example FlhDC<sub>SE</sub> is gray. Error bars show the standard error of the mean. See text for values of the calculated slopes using the excel built-in function SLOPE to highlight the impact of FlhC<sub>EC</sub> in each isolated complex.

maximal activity of  $P_{flgA}$  and  $P_{fliC}$  can reach 40–50% of  $P_{tetA}::flhDC$  expression for  $P_{tetR}$  strains, this results in an average of 2 flagella per cell. This suggests that even though the majority of the literature states that *E. coli* and *S. enterica* produce between 4 and 8 flagella per cell, only 1 or 2 per cell is needed for an optimal output of the system with respect to motility agar assays. This conclusion correlates with the observation that swimming speed does not depend on flagella numbers in *E. coli*<sup>31</sup>.

It has been shown that FlhT interacts with FlhC and that in *S. enterica* the output of this circuit is to destabilize FlhD<sub>4</sub>C<sub>2</sub> complexes that are not bound to DNA. Our data suggests that this level of regulation does not impact *E. coli* FlhC. The nature of the adaptability needed by the favourable conditions to drive motility in *E. coli* may have led to the FlhT regulatory input becoming less critical. Indeed, the specific amino acid substitutions between FlhC<sub>EC</sub> and FlhC<sub>ST</sub> merits further investigation, outside the focus of this study, to determine whether this can be defined by a single substitution or requires the combination of the changes observed between these two proteins (Figure S1). Similarly, the impact of FlhZ regulation becomes apparent for FlhD<sub>EC</sub> containing complexes when we assess flagellar numbers. FlhZ regulates the transcription of *rflP* in *S. enterica*<sup>27</sup>. It is plausible that the impact in changing *rflP* regulation is the source of this differentiation, especially as RflP is proposed to interact with FlhD<sub>SE</sub>. Furthermore, we know that *rflP* is not expressed in model *E. coli* strains, strengthening the argument that FlhD<sub>EC</sub> has adapted to the absence of RflP or vice versa FlhD<sub>SE</sub> to RflP. However, regulation of flagellar gene expression in *S. enterica* via FlhZ must take in to consideration other regulators such as HilD and its impact on *flhDC* gene expression<sup>9,28,29</sup>.

Importantly our analysis shows that even though these two systems are genetically similar, investigation of FlhD<sub>4</sub>C<sub>2</sub> activity identifies subtle but key differences into how the FlhD<sub>4</sub>C<sub>2</sub> complex is modulated in two closely related species. We argue that this is a valid example of the caution needed in the age of synthetic biology to exploit heterologous systems in alternative species or chassis. Our data shows that even systems showing significant synteny may not behave in exactly the same manner and due diligence is required in making assumptions based on heterologous expression.

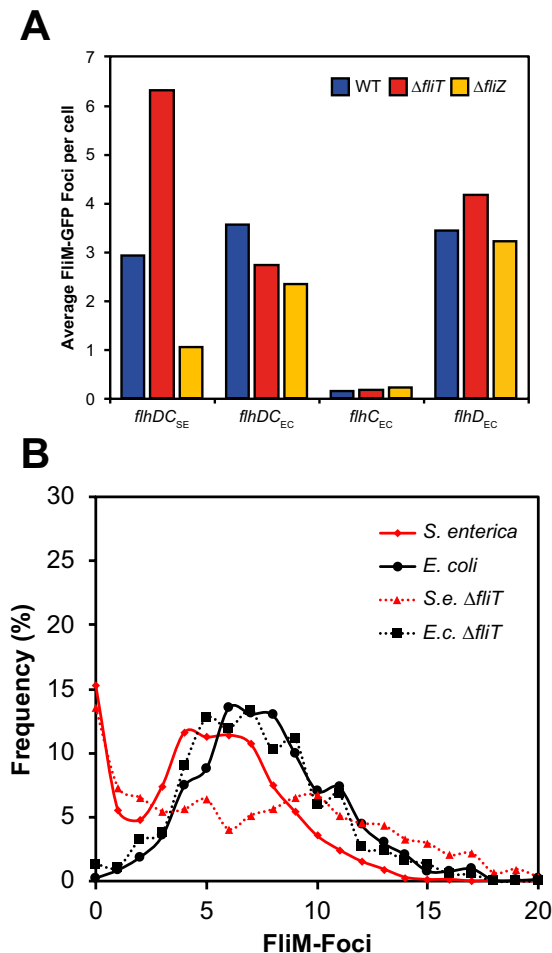

**Figure 6.** Impact of protein stability regulators of FlhD<sub>4</sub>C<sub>2</sub> on flagellar numbers as defined by FliM-foci. Quantification of FliM-foci was performed using the semi-automatic protocols defined with in Microbetracker. (A) Wild Type foci distribution; (B)  $\Delta clpP$ ; (C)  $\Delta rfiP$ . All line and symbol colours reflect the same complex associated with data shown in Figs 2, 4 and 5 for continuity, for example *S. enterica* (FlhDC<sub>SE</sub>) is gray.

## Materials and Methods

**Bacterial Strains and Growth conditions.** *S. enterica* and *E. coli* strains used in this study have been previously described elsewhere<sup>12,15,17,30</sup>. This study used *S. enterica* serovar Typhimurium strain LT2 as the chassis for all experiments. *E. coli* genetic material was derived from MG1655. All strains were grown at either 30 °C or 37 °C in Luria Bertani Broth (LB) either on 1.5% agar plates or shaken in liquid cultures at 160 rpm<sup>17</sup>. Antibiotics used in this study have been described elsewhere<sup>32</sup>. Motility assays used motility agar<sup>17</sup> incubated at 37 °C for 6 to 8 hours. Motility swarms were quantified using images captured on a standard gel doc system with a ruler in the field of view and quantified using ImageJ to measure the vertical and horizontal diameter using the average as the swarm size. All motility assays were performed in triplicate using single batches of motility agar.

**Figure 7.** FliT and FliZ regulation reflects when FlhC<sub>EC</sub> or FlhD<sub>EC</sub> are present. **(A)** FliM-Foci quantification is consistent with the observed motility phenotype of  $\Delta fliT$  mutants. For  $\Delta fliZ$  FliM-foci numbers discriminate between the source of FlhD, FlhD<sub>SE</sub> exhibits a consistent drop in foci while FlhD<sub>EC</sub> containing strains show comparable foci averages. **(B)** Testing the hypothesis that  $\Delta fliT$  mutants respond differently in *E. coli* compared to *S. enterica*. Note: this experiment in **(B)** uses the species *E. coli* and *S. enterica* not engineered replacements.

**Genetic Manipulations.** For the replacement of *flhDC* coding sequences the modified lambda red recombination system described by Blank *et al.* (2011) was used<sup>33</sup>. Deletion of *clpP*, *rflP*, *fliT* and *fliZ* was performed using the pKD system described by Datsenko and Wanner (2000)<sup>34</sup>.  $P_{tetA}/P_{tetR}$  replacements of the  $P_{flhDC}$  region was also performed using Datsenko and Wanner (2000) with the template being Tn10dTc<sup>35</sup>. For Blank *et al.* (2011) replacement experiments we used autoclaved chlortetracycline instead of anhydrotetracycline as described for the preparation of Tetracycline sensitive plates<sup>36</sup>. All other gene replacements were performed as previously described<sup>17</sup>. All primers used for these genetic manipulations are available on request.

**Quantification of flagellar gene expression.** Flagellar gene expression assays were performed using the plasmids pRG39::cat ( $P_{flhC}$ ) and pRG52::cat ( $P_{flhA}$ )<sup>15</sup>. Both plasmids were transformed into strains using electroporation. Gene expression was quantified as described previously and analysis was based on a minimum of  $n = 3$  repeats for each strain tested<sup>15</sup>.

**Quantification of FliM-GFP foci.** FliM-GFP foci were quantified using Microbetracker on images captured using a Nikon Ti inverted microscope using filters and exposure times described previously<sup>14</sup>. Strains were grown to an OD<sub>600</sub> of 0.5 to 0.6 and cells immobilised using a 1% agarose pad containing 10% LB<sup>14,17</sup>. For each strain a minimum of 5 fields of view were captured from 3 independent repeats. This allowed analysis of approximately 400–1000 cells per strain. For the comparison of FliM foci in *E. coli*  $\Delta fliT$  to *S. enterica*  $\Delta fliT$  shown in Fig. 7B the chemostat growth system described by Sim *et al.* (2017) was used. For this experiment the growth rate of both strains was similar to batch culture in LB at 37 °C where the media used was a Minimal E base salts, a minimal media previously described<sup>14,17</sup>, supplemented with 0.1% Yeast extract and 0.2% glucose.

**Purification of FlhD<sub>4</sub>C<sub>2</sub> complexes.** Purification of proteins complexes was based on previously described methods<sup>17</sup>. Wild type FlhD<sub>4</sub>C<sub>2SE</sub> was purified using pPA158. The other 3 complexes were purified from plasmids generated using the New England Biolabs NEBuilder DNA Assembly kit on the backbone of pPA158. The

*E. coli* strain BL21 was used for all protein induction experiments prior to protein purification using either a pre-equilibrated 5 ml His-trap column or a 5 ml heparin column (GE Healthcare). Proteins were visualised using Tricine-based SDS polyacrylamide gel electrophoresis and standard comassie blue staining<sup>47</sup>.

**Electrophoretic mobility shift assay (EMSA).** All EMSA assays were performed using Ni++ (his-trap) purified proteins as this allowed analysis of all four complexes (Fig. 5A). Buffer exchange from elution buffer to a 100 mM Tris-HCl, 300 mM NaCl 1 mM DTT (pH 7.9) buffer was performed through 10 cycles of protein concentration in VivaSpin columns with 20 ml buffer reduced to 5 ml per round of centrifugation at 4500 rpm. A protein concentration range of 100 to 700 nM was used with 80 ng/ml of a PCR product containing P<sub>flgAB</sub> from *S. enterica*. After incubation bound and unbound DNA were resolved using 5% acrylamide gels made with 1x TBE buffer. Quantification of gel images was performed using ImageJ.
